

# Fire Hazard Severity Zone Remap

Using Localized Severe Fire Weather Inputs in  
Statewide Hazard Mapping in California

Board of Forestry April 7, 2021

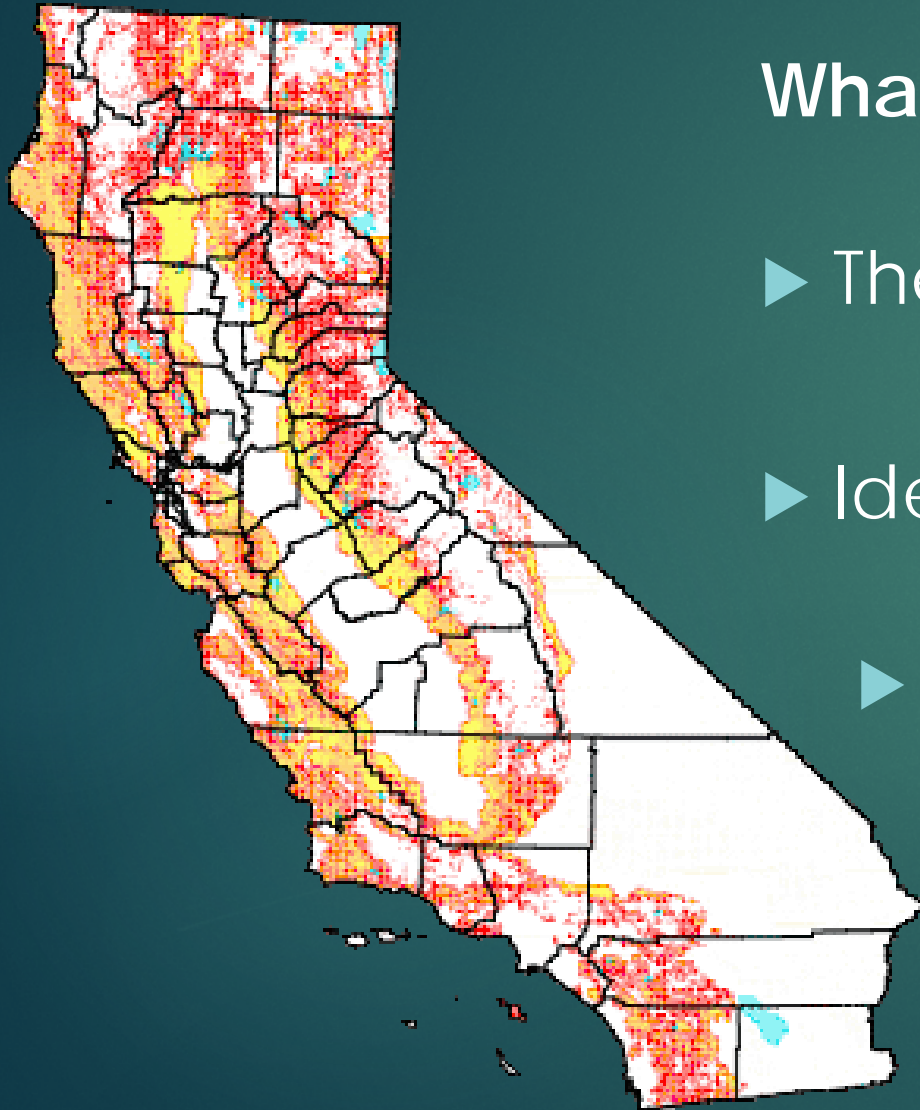

**Daniel Berlant and David Sapsis**

Jamie Lydersen, James Spero, Mark Rosenberg Tiffany Meyer, Travis Bott, Scott Witt, Nic Johnson

# Fire Hazard Severity Zone Remap

## What are the Zones?

- ▶ The maps are required by law
- ▶ Identify levels of fire hazard
  - ▶ 3 Levels (Moderate, High, & Very High)
    - ▶ all 3 in State Responsibility Area
    - ▶ Only Very High in Local Responsibility Area

# Fire Hazard Severity Zone Remap

How are the zones determined?

- ▶ Developed using a science-based model that assigns a hazard score based on the factors that influence fire likelihood and fire behavior.
- ▶ Factors: fire history, vegetation, topography, climate, ember production and movement

# Fire Hazard Severity Zone Remap

## What is the map for?

- ▶ Building standards for new construction in the Wildland-Urban Interface
- ▶ Natural hazard real estate disclosure
- ▶ Property development standards such as road widths, water supply and signage
- ▶ Consideration in city and county general plans

# Fire Hazard Severity Zone Remap

## Remap Objectives:

- ▶ Update the scientific factors that determine the hazard ratings including new local climate data and improved fire spread modeling.
- ▶ Provide opportunity for validation in the modeling
- ▶ Publish approved State Responsibility Area map
- ▶ Publish and submit Local Responsibility Area maps

# Fire Hazard Severity Zone Remap

## Timeline:

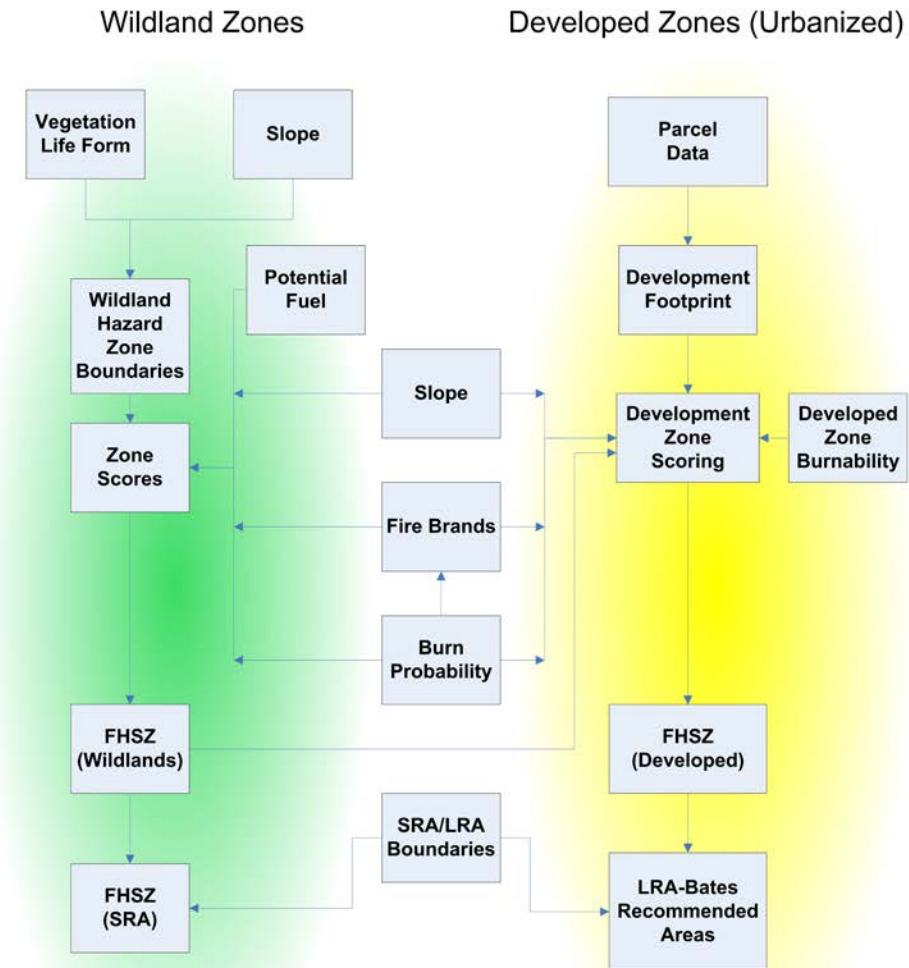

- ▶ Current maps were developed in 2007-2010.
- ▶ Over the past several years staff have been building the new science model.
- ▶ Summer 2021 – Adopt map in State Responsibility Areas (SRA) into regulations.
- ▶ Fall 2021 – Begin Local Responsibility Area(LRA) remap

# 2007 Model

- ▶ Wildland centric but zones non-wildland developed (urbanized) areas
- ▶ Hazard = probability x Intensity
- ▶ Uses climax fuel construct
- ▶ Uniform fire weather
- ▶ Urban model included simplified firebrand distribution model and urban vegetation factors
- ▶ Scaled to produce VH bands from roughly 0.25-1 km in depth.

## FIRE HAZARD SEVERITY ZONING MODEL STRUCTURE

# Model Results/Performance

SRA

Very High 12.5 M acres  
High 10.6 M acres  
Moderate 7.9 M acres

LRA VH 865,000 acres  
~190 jurisdictions adopting zones

# Structure Damage by FHSZ class

2013-2020

N= 49,504

■ Moderate = 6,061   ■ High = 6,933   ■ Very High = 33,814   ■ Out = 2,696

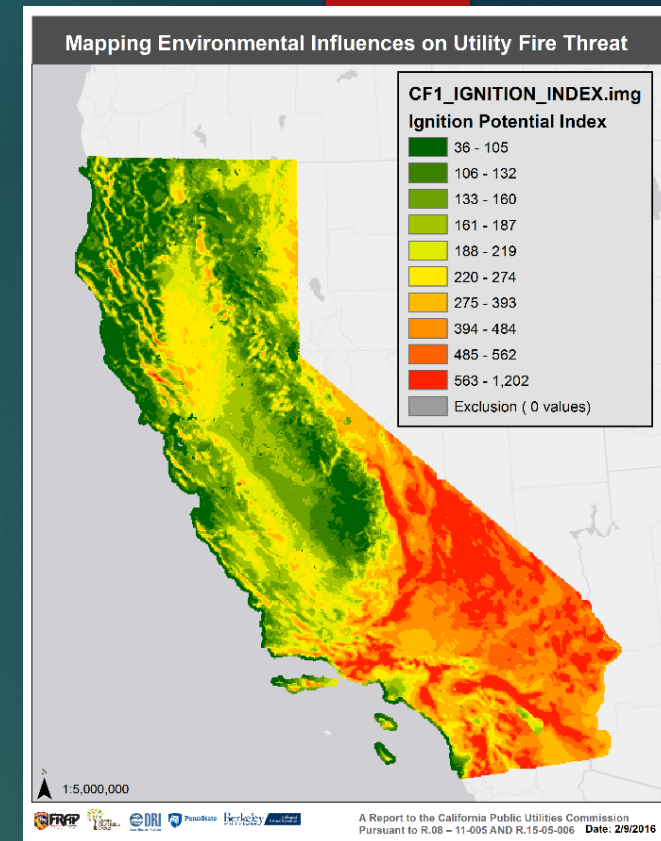

# New Updates

- ▶ Updated burn probabilities for wildland areas (inclusive of 2020 fires)
- ▶ Updated fire environment footprints (urban/developed)
- ▶ Updated Vegetation density for urban areas
- ▶ Inclusion of slope in the urban zoning model
- ▶ **Localized fire weather used in both wildland and urban models**
- ▶ **New firebrand production and transport model using discrete local wind vector distributions**

# Bringing Local Weather In

- ▶ Data Provided by Desert Research Institute using standard fire forecast settings (same as provided to GACC forecasts)
- ▶ Weather Research and Forecasting (WRF) reanalysis
  - ▶ 2003-2018 (16 years)
  - ▶ 2km grid resolution
  - ▶ Hourly; 24 hours; 365 days
  - ▶ Main fire weather variables subject to bias correction process
  - ▶ Quantile filters applied to cell-based (local) populations
  - ▶ 90<sup>th</sup> %tile Energy Release Component (ERC -G) dryness -- ~36 driest days per year
  - ▶ 95<sup>th</sup>%tile Fosberg Fire Weather Index (FWI) – for those driest days, select top 5% hourly records (dry and windy!) ~600 records for each cell

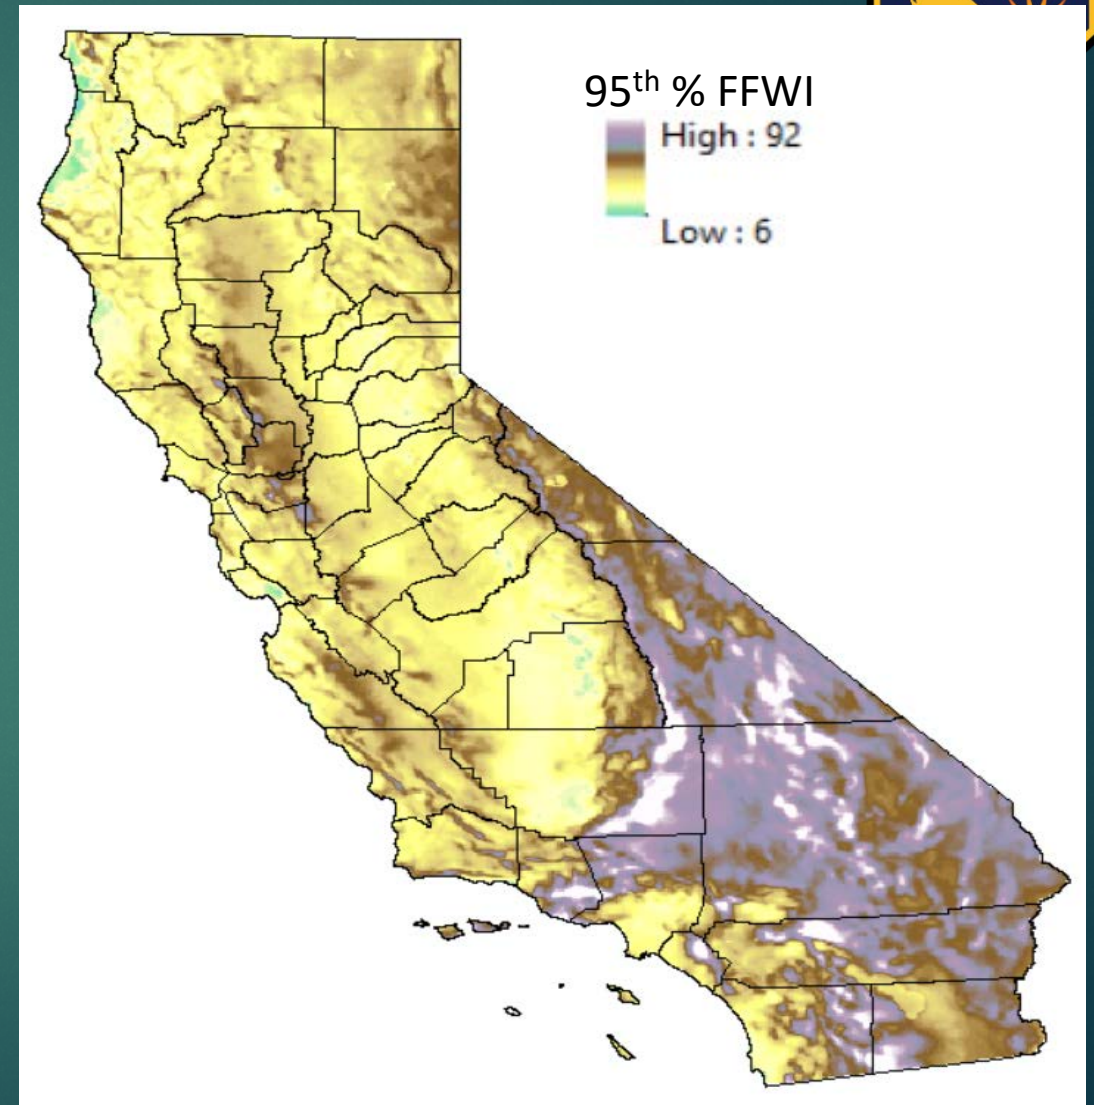

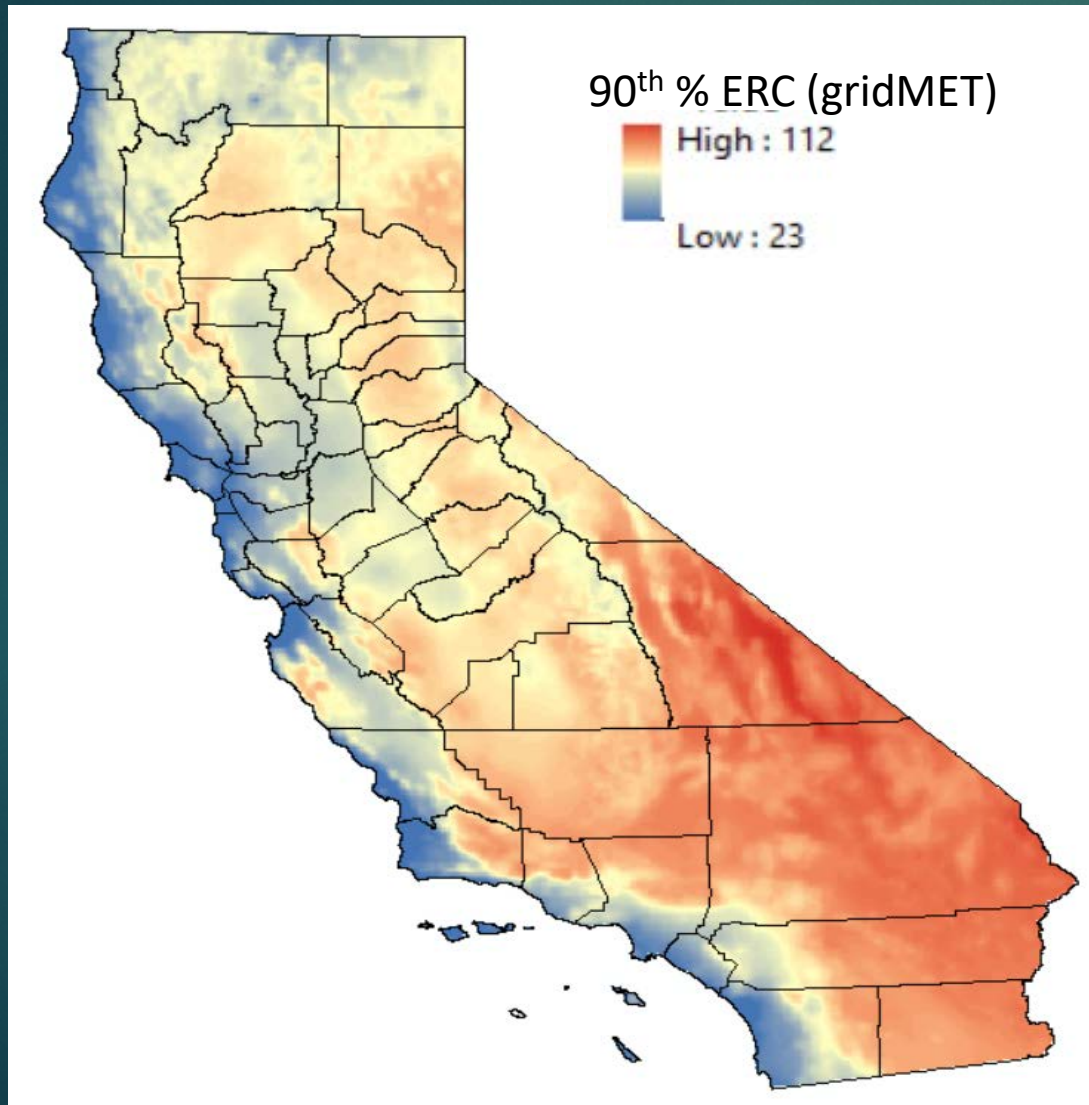

# Weather filtering mechanics

- ▶ ERC-G as dryness filter ---~72 driest days per year
- ▶ For all those dry days, we selected the top 5% of hourly FFWI values
- ▶ 95%tile value FFWI used to modify wildland intensity scores based on stock weather inputs (3,4,5,70% moisture content, 7 mph windspeed)
- ▶ All winds in the final selection set were translated into wind vector classes and associated frequency distributions
- ▶ 10 mph speed classes; 12 azimuth classes

Wind Vectors for point 337\_77

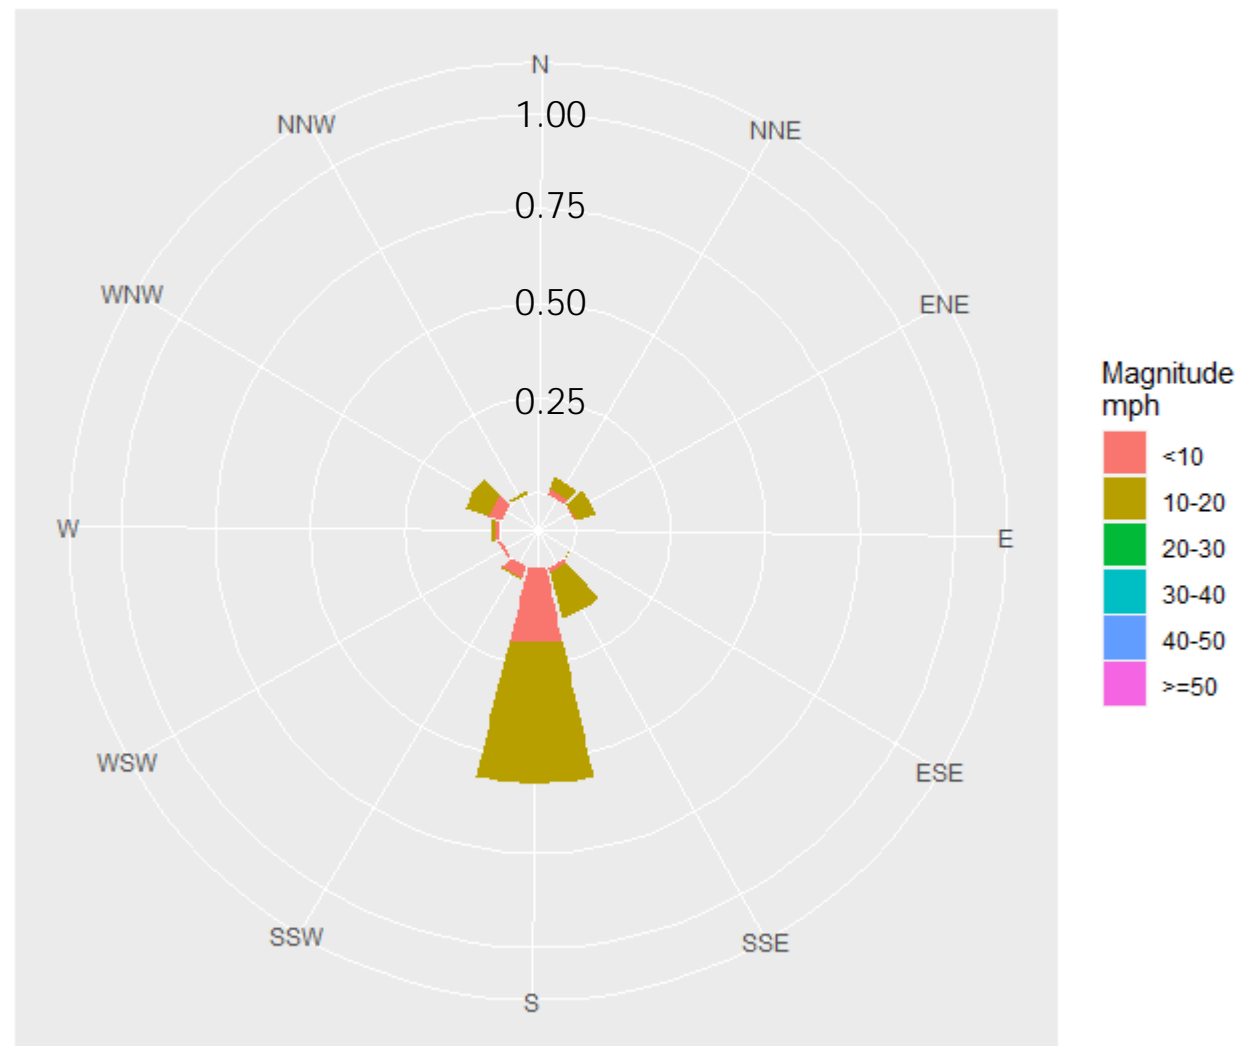

# Example: WRF Cell wind distributions

## Wind Vectors for point 144\_384

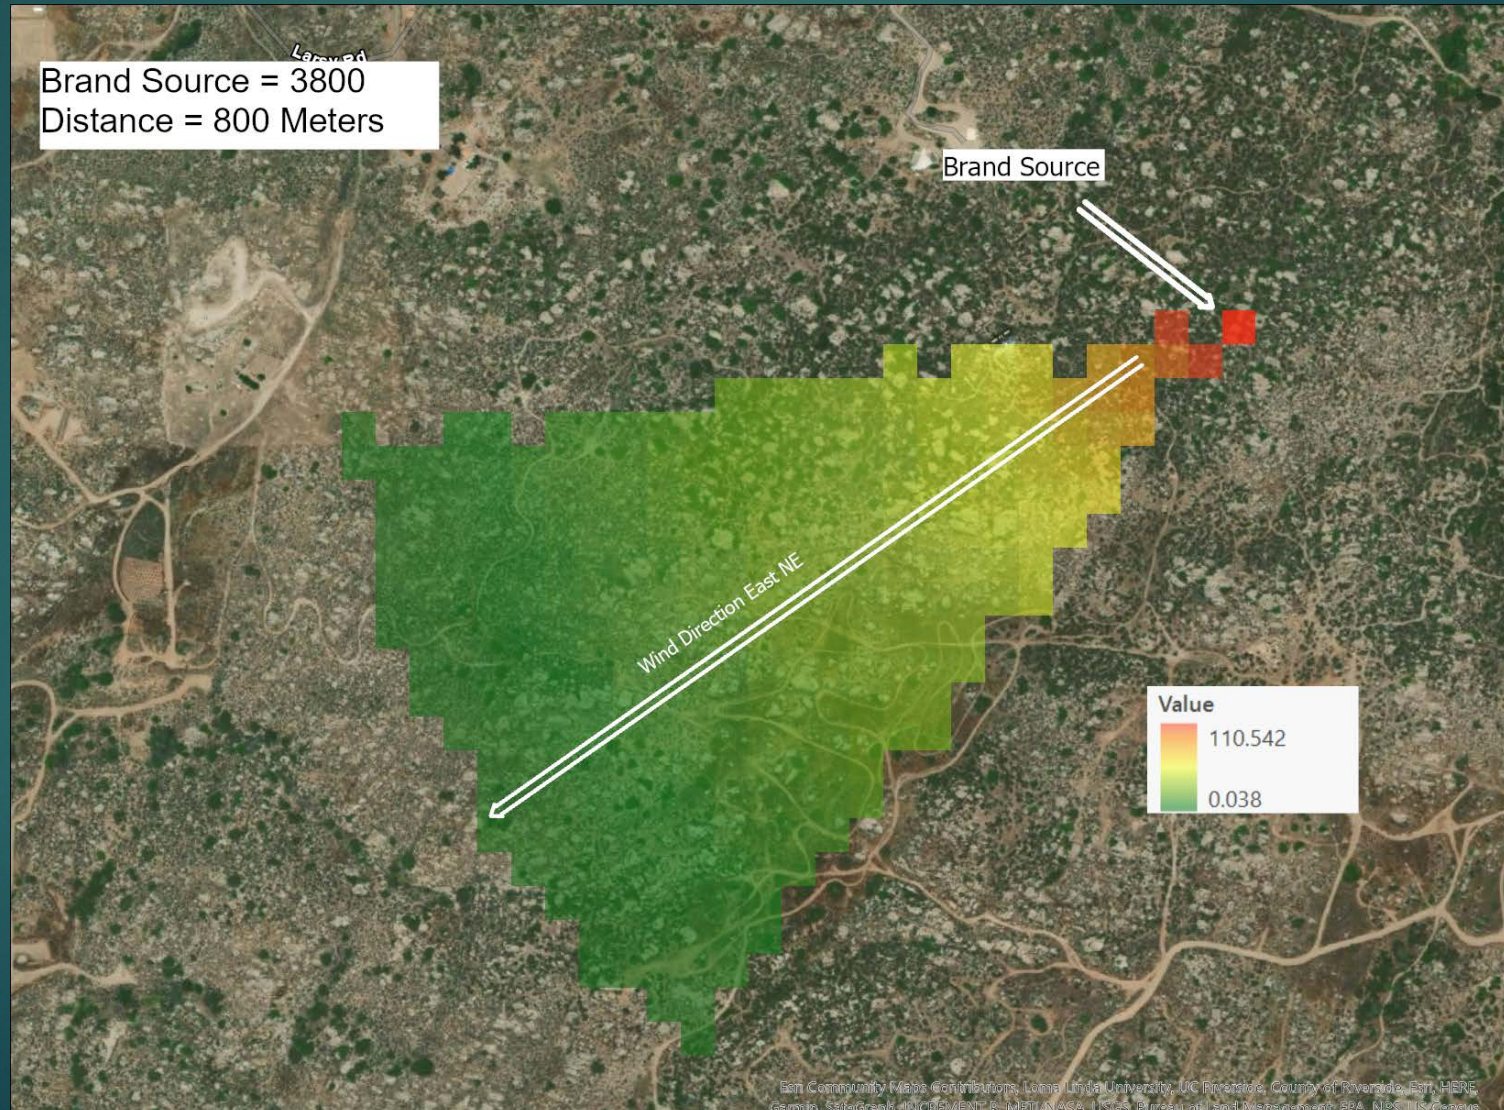

# Firebrands

- ▶ Cell-based generation of brands lofted based on fuel type and fire intensity
- ▶ Number lofted = (brand\_loft) x p(fire) x (scaling factor)
- ▶ Firebrand transport derived from focal-sum kernel that distributes the source brands downwind according to generalized negative exponential decay and scatter pattern
- ▶ Kernels for 100, 200, 400, 800, and 1500m maximal distance
- ▶ Orientation of kernels follows wind vector distribution
- ▶ Total of 60 size/direction kernels
- ▶ Kernel assignment depends on winds, fuels, and fire type (crown vs surface line-fire)

# Single Vector – 800m/East NE wind
